## Apêndice

### A.1

#### A condição de primeira ordem no caso geral

O objetivo dos pais é encontrar a combinação de consumo ( $x$ ), número de filhos ( $n$ ), horas dedicadas à saúde ( $t_s$ ) e à educação ( $t_h$ ) dos filhos, horas dedicadas à trabalho no mercado ( $t_l$ ) e o montante de capital humano dos filhos ( $h_c$ ) que maximize a utilidade

$$U = x^{\alpha_1} (ns)^{\alpha_2} (h_c + h_0)^{\alpha_3}$$

sujeita às restrições:

$$h_c(t_h, t_s) = A(s(t_s))(h_p + h_0)t_h \quad (\text{A-1})$$

$$T = t_l + n(\mu + t_s + t_h) \quad (\text{A-2})$$

$$t_l(h_p + h_0) = x + n(\rho + \sigma t_s) \quad (\text{A-3})$$

onde

$$s(t_s) = s_0 + \delta(1 - \exp(-t_s)).$$

é a tecnologia doméstica de saúde tal que  $\delta \equiv s_1 - s_0$ .

Aplicando o log na função de utilidade dos pais e definindo, respectivamente,  $\mathcal{L}$ ,  $\lambda$ ,  $\theta$  e  $\psi$  como o lagrangeano e os multiplicadores associados à cada restrição, temos:

$$\begin{aligned} \mathcal{L} = & \alpha_1 \log x + \alpha_2 \log n + \alpha_2 \log s(t_s) + \alpha_3 \log(h_c + h_0) \\ & + \psi A[s(t_s)]t_h(h_p + h_0) + \theta[T - t_l - (\mu + t_s + t_h)n] \\ & + \lambda[t_l(h_c + h_0) - c - (\rho + \sigma t_s)n] \end{aligned}$$

Supondo solução interior para  $x$ ,  $n$  e  $t_l$ , a condição de primeira ordem

será dada pelo seguinte sistema de equações:

$$\frac{\alpha_1}{x} = \lambda \quad (\text{A-4})$$

$$\frac{\alpha_2}{n} = \theta(\mu + t_s + t_h) + \lambda(\rho + \sigma t_s) \quad (\text{A-5})$$

$$\alpha_2 \frac{s'(t_s)}{s(t_s)} + \psi \frac{dA}{ds} s'(t_s) t_h (h_p + h_0) \leq \theta n + \lambda \sigma n \quad (\text{A-6})$$

$$\theta = \lambda(h_p + h_0) \quad (\text{A-7})$$

$$\psi A[s(t_s)](h_p + h_0) \leq \theta n \quad (\text{A-8})$$

$$\frac{\alpha_3}{h_c + h_0} \leq \psi \quad (\text{A-9})$$

A partir das equações A-2, A-3, A-4, A-5 e A-7, chega-se aos valores ótimos do consumo  $x$  e dos multiplicadores  $\lambda$  e  $\theta$ :

$$x = \frac{\alpha_1}{\alpha_2 + \alpha_3} T(h_p + h_0) \quad (\text{A-10})$$

$$\lambda = \frac{\alpha_1 + \alpha_2}{T(h_p + h_0)} \quad (\text{A-11})$$

$$\theta = \frac{\alpha_1 + \alpha_2}{T} \quad (\text{A-12})$$

As três equações aplicam-se tanto para o equilíbrio malthusiano quanto para o equilíbrio moderno.

### A.1.1

#### Condição de primeira ordem no equilíbrio malthusiano

Vamos agora caracterizar o equilíbrio malthusiano, ou seja, aquele em que os pais não investem no capital humano dos filhos. Nesse equilíbrio, o capital humano dos pais se restringe ao capital humano básico, de forma que  $h_p = 0$ , e não há investimento no capital humano dos filhos, de forma que os pais irão escolher  $h_c = t_h = 0$ . Impondo essas hipóteses na condição de primeira ordem temos que A-7, A-8, A-9 e A-11 implicam

$$n(t_s) = \left( \frac{\alpha_2}{\alpha_1 + \alpha_2} \right) \frac{Th_0}{\rho + \mu h_0 + (\sigma + h_0)t_s} \quad (\text{A-13})$$

enquanto A-5, A-6 e A-7 implicam

$$R(t_s) \leq C(t_s)$$

onde  $R(t_s) \equiv s'(t_s)/s(t_s)$  e  $C(t_s) \equiv [(\rho + \mu h_0)/(\sigma + h_0) + t_s]^{-1} = -n'(t_s)n(t_s)$ , sendo que a desigualdade estrita irá prevalecer na solução de canto  $t_s = 0$ .

As duas condições acima determinam, respectivamente, o número ótimo de filhos e de horas dedicadas aos cuidados com a saúde de cada um deles no regime malthusiano.

### A.1.2

#### **Condição de segunda ordem no equilíbrio malthusiano**

A verificação da condição de segunda ordem é facilmente obtida se notarmos que no equilíbrio malthusiano o problema dos pais se simplifica. No regime malthusiano,  $h_p = h_c = t_h = 0$  e  $x = \frac{\alpha_1}{\alpha_1 + \alpha_2} Th_0$ . Substituindo esses valores na função de utilidade dos pais, vemos que problema se torna simplesmente encontrar o número de horas dedicadas à saúde cada filho de forma a maximizar

$$\ln(n(t_s)) + \ln(s(t_s))$$

onde  $n$  é dado por A-13. Portanto, a condição de segunda ordem para a maximização é que a função acima seja côncava em  $t_s = t_s^*$ :

$$\frac{d^2}{dt_s^2} [\ln(n(t_s^*)) + \ln(s(t_s^*))] = \frac{d}{dt_s} \left[ \frac{n'(t_s^*)}{n(t_s^*)} + \frac{s'(t_s^*)}{s(t_s^*)} \right] < 0. \quad (\text{A-14})$$

Com um pouco de álgebra, é possível mostrar que a condição de segunda ordem pode ser reescrita como:

$$\left( \frac{n'(t_s^*)}{n(t_s^*)} \right)^2 - \left( \frac{s'(t_s^*)}{s(t_s^*)} \right)^2 - \frac{s'(t_s^*)}{s(t_s^*)} < 0 \quad (\text{A-15})$$

Pela condição de primeira ordem, os dois primeiros termos se cancelam e, como o terceiro termo é positivo, a condição de segunda ordem é satisfeita.

### A.2

#### **Equilíbrio com crescimento**

No equilíbrio com crescimento, o capital humano básico se torna assintoticamente irrelevantes; assim, podemos supor  $h_0 = 0$ . Além disso, considerando apenas soluções interiores, A-6, A-8 e A-9 da condição de primeira ordem se tornam igualdades. Substituindo A-9 em A-8 e utilizando A-1, chega-se à solução para o número de filhos:

$$n = \frac{\alpha_3}{\alpha_1 + \alpha_2} \frac{T}{t_h}.$$

Substituindo o resultado acima na equação A-5 e utilizando as soluções para os multiplicadores  $\lambda$  e  $\theta$  dadas pelas equações A-11 e A-12, respectiva-

mente, encontramos que o tempo investido na formação do capital humano dos filhos é dado por

$$t_h = \frac{\alpha_3}{\alpha_1 - \alpha_2} \left( \mu + t_s + \frac{\rho + t_s}{h_p} \right)$$

Como no equilíbrio moderno há acumulação de capital humano com retornos constantes, então  $h_p \rightarrow \infty$ ; logo o último termo dentro do parênteses desaparece; portanto:

$$t_h = \frac{\alpha_3}{\alpha_1 - \alpha_2} (\mu + t_s)$$

Finalmente, na equação A-6, colocondo-se  $s'/s$  em evidência e substituindo as equações para  $n$ ,  $t_h$ ,  $\lambda$  e  $\theta$ , chega-se a:

$$(\alpha_2 + \alpha_3 \epsilon_s^A) \frac{s'(t_s)}{s(t_s)} = \frac{\alpha_2 - \alpha_3}{\mu + t_s}.$$
